Table 1: Table to capture the history of the document

Introduction

0.1 Purpose

The purpose of this document is to describe the implementation of the OpenBazaar that was described in the Software Requirements Specification (SRS) document completed earlier this semester. It aims to outline a design that will meet all of the functional and non-functional requirements described in the SRS. It is also meant to be a template for creating the Module Interface Specification document, MIS, which will describe the modules in further detail.

The design principle being used to implement this project is the principle of information hiding which was first described by David Parnas (Parnas,1972). The idea behind this design strategy is that each module contains some secret, essentially hiding a design decision from the rest of the system. As a result of this method of modularization, aspects of the system that are likely to change are hidden within a module and, when changed, do not affect the rest of the modules. This is important for any software design as technology is constantly evolving and software often needs to be updated in order to remain relevant.

This document is intended for future developers and designers who wish to improve or better understand the design of the OpenBazaar.

0.2 Scope

The purpose of this project is to design and implement OpenBazaar, a free, open market run through a peer-to-peer network that aims to replace centralized services such as eBay or Amazon by providing a means in which to participate in online trade. Major users of the OpenBazaar include buyers, sellers, and notaries. This document describes the implementation details of all major functions that create the OpenBazaar, from every type of user's perspective: buyers, sellers, and notaries.

Anticipated and Unlikely Changes

This section is intended for all possible changes that may occur to the system. They will be listed in order from most likely to least likely.

0.3 Anticipated Changes

AC1 The hardware the OpenBazaar runs on

AC2 The operating system the Openbazaar runs on

AC3 A user's information such as their: public and private key, role (buyer, seller, notary), IP Address, Bitcoin information, digital signature, GUID,

market(items,price,description), and personal settings (i.e. display picture)

AC4 The algorithm to search for nodes on the network

AC5 Personalization options for a user market

0.4 Unlikely Changes

UC1 Bitcoin as a medium of exchange

UC2 Ricardian contract structure

Module Hierarchy

This section outlines the modules used in the implementation of the application. Each module is organized and decomposed according to the type of secret it contains.

M1 Server/Network Module

M2 Connector Module

M3 GUI Module

M4 Node Module

M5 Identity/Backend Module

M6 Ricardian Contract Module

M7 DHT/Routing Table Module

M8 Settings Module

M9 Store Module

M10 Notary Module

M11 Bitcoin Module

Connection Between Requirements and Design

Module Decomposition

Below is a decomposition of each module in the application design, with details of the module's provided services and encapsulated secrets.

Level 1	Level 2	Level 3
Hardware-Hiding Module	GUI Module	
Behaviour-Hiding Module	Node Module	Published Contract Module
	Identity Module	Settings Module
		Store Module
		Notary Module
		Active Contract Module
	DHT/Routing Table Module	
Software Decision Module	Algorithms Module	
	Initialization Module	

Table 2: Module Hierarchy

0.5 Hardware Hiding Modules

1. GUI Module

- **Secret:** The underlying machine hardware and operating system environment for the application.
- **Services:** The GUI module is responsible for handling user interaction with the system. Provides controllers which take inputted data and relay to the frontend-to-backend connector for further analysis and use.
- **Implemented by:** The module has been partly implemented via the PyQt4 framework. Implementation will be done by creating components which inherit from classes in the PyQt4 module.

0.6 Behaviour Hiding Modules

1. Identity/Backend Module

- **Secret:** The underlying data and behaviour requirements of the system.
- **Services:** The backend module is primarily responsible for holding all of the modules relevant to system requirements. It holds user data including all given personalization data, trade contracts and application settings. User interaction will pass through the connector module to this module.

2. Node module

- **Secret:** Information related to the peer-to-peer networking component of the application.
- **Services:** This module provides all data and behaviours that make a machine a valid network node.

3. DHT Module

- **Secret:** The contents and implementation of the distributed hash table and routing tables for the Kademlia peer-to-peer network.
- **Services:** The DHT module provides information about the distributed hash table used for networking. The module does node lookups and returns information about

Description

The OpenBazaar modules are broken up into logical components, abstracting away portions of the application that do not depend on one another. The first logical decomposition of the application is to abstract the details of the graphical user interface from the details of the data implementation. Each of these respective components will run as its own thread in the application environment. The data implementation can then be manipulated and accessed by the user via interaction with the GUI. To facilitate this interaction a connector module will be created. This module will expose an interface for the GUI to interact with that submits and returns data for graphical display to the user.

Front-End Client

- BazaarMain
 - Inherits from QMainWindow in PyQt4 module
 - All other GUI components are contained within the QMainWindow
 - Instance variable menuBar holds the menu bar of the application
-

Back-End Server

-

Server-Client Connection

-
